# 1 Abstract

Current prominent web traffic analytics systems such as Google Analytics report traffic per website, given certain filtering criteria. Such systems are typically geared to system administrators who use the data to identify patterns and possibly assist management in strategy making. For news sites, this may mean analyzing the traffic on a news article and where most of the readers came from. The end users, however, will at best see metrics such as social likes and shares. But, what if we could provide the end users a near real-time metrics map of the entire news site they are visiting? What if they could navigate based on traffic patterns, as opposed to having to follow the common front page layout specified by the news editors? This is the system I built - a web-based, interactive visualization that shows the near real-time metrics of a select news site. In the first stage, I created a database to house the webtrics that I wanted to capture. I then created a server-side library that could be included into any website or web application. This library hooks into my database and efficiently captures the hits' metadata (IP addresses, geographic origins, etc.) against the given news site. I then built the "business logic" of the data and information that I wanted to capture. This includes algorithms that produce the refined data and metrics to be ultimately communicated to the end user. My final step amounted to the creation of an interactive visualization that shows near real-time user web traffic in each of the registered articles of the given news site.

**Figure 1 –** The user visits a news site and loads an interactive web visualization which visualizes web traffic and attention span across the visitors' origin geographic areas. The visualization also includes previews of the articles and a way to link back to the articles' pages.

## 2 Thesis Project Description

The system that I built hooks into a Wordpress news website, captures web metrics, and visualizes these metrics in an interactive web-based visualization. The visualization is targeted towards both webmasters and end readers.

On the server side scripting end, I built PHP classes that were included in the top of the news site's file(s). The code registered every visiting IP address. For the scope of this project, I have defined a hit/visit as a unique IP address hitting the news site within an allowed limit of revisit time in seconds. That is, I created a mechanism that allows the administrator to set a threshold, in seconds, as to when the next visit should be counted as a new hit. For example, if this variable was set to 60 seconds, and a visitor refreshed the article page as many times as possible within 60 seconds, then all the page refreshes would be collectively counted as 1 hit. The goal here was to have more accurate readings. This counters against people constantly refreshing an article page to inflate the metrics for that site; similarly, it counters against automated scripts that could mimic human behavior and attempt to create many mock visits to the same article within a very short period of time.

I built the relational database using normalization tenets. The database is in the 3rd normal form.

Here are the technologies that I used in building my system:

- MySQL for the relational database that houses the web metrics
- PHP for the server-side script that stores and retrieves the data from the database
- HTML 5 for laying out the basic components of the visualization - for example, the controls box
- SVG to markup the visualization elements
- CSS3 for styling the HTML and SVG elements
- JavaScript to manipulate the DOM (Document Object Model) and to load data from the server side

- D3.js (Data-Driven Documents) to facilitate the manipulation of the data in the visualization
- jQuery to shorthand some lengthy Javascript functions

The domain that I targeted is **online news media**. I captured the below data, as far back as 31 days:

- Visitor hits to a given article. Each hit is defined by a unique timestamp and IP address
- Geographical origin of the visitors to a given article
- Amount of time spent reading the article for a given hit

The interactive visualization, enabled 4 tasks:

1. To compare articles' hits and reader attention spans for any period within the last month, given a select category
2. To preview each article's thumbnail, title, and excerpt
3. To contrast the geographic distribution of hits and attention of up to 2 articles
4. To navigate to the full article counterpart on the subject news website

As for interactivity, the visualization enabled the following:

- Hovering over article elements to preview the thumbnail, title, and excerpt of the body content
- Clicking on an article element to display a table that shows the geographic distribution of the number of hits and attention span for that article
- Filtering the data via a controls box. The controls box allows the user to select a desired news category, to filter by date range, and to toggle some context-related settings

The final product was geared towards the conventional news site structure, where categories are enumerated (e.g. sports, health, science, politics, etc.), and where articles are listed under their pertinent categories. The below illustrate my initial sketches that were used to shape the final product.

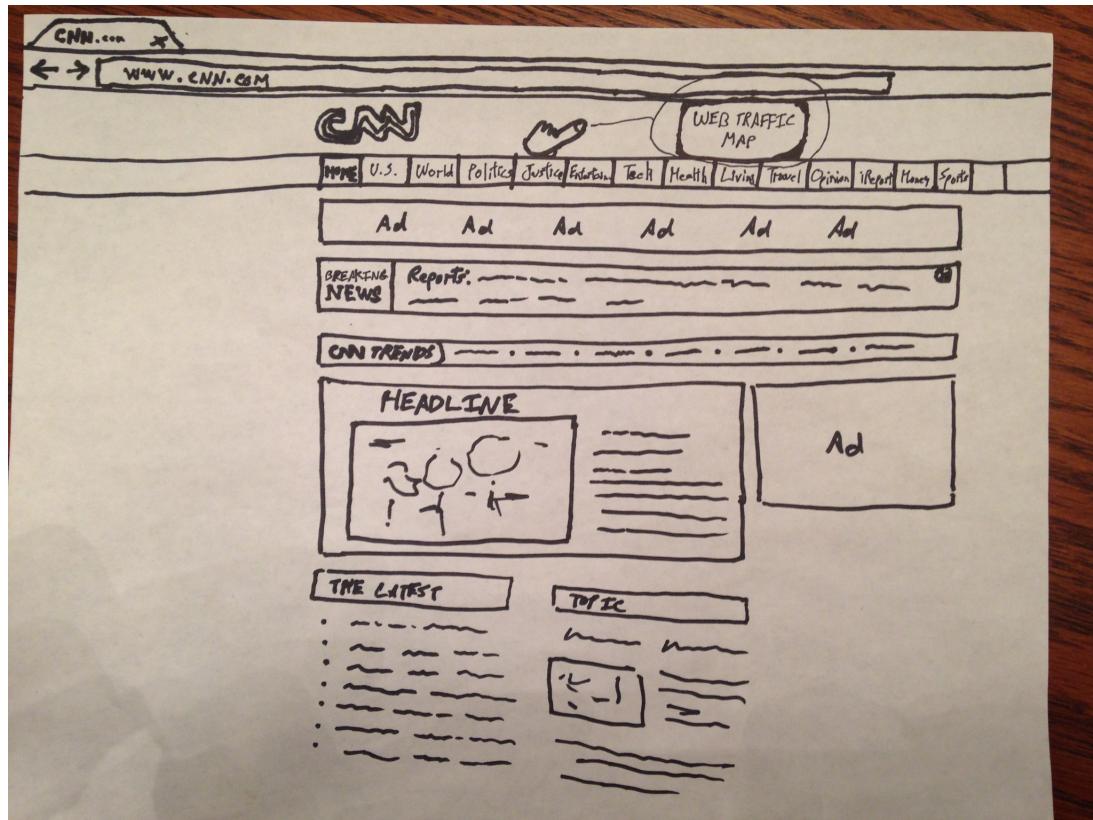

Figure 2 – On a news site like CNN, for example, there would reside a link to the near real-time visualization.

Figure 3 – A potential way of visualizing the near real-time traffic. Here, the articles are encoded by lines. Each line's length signifies how much traffic a select article has. Hovering over said line/article invokes a details-on-demand window - showing the title, a picture snapshot, and an excerpt from the article's body.

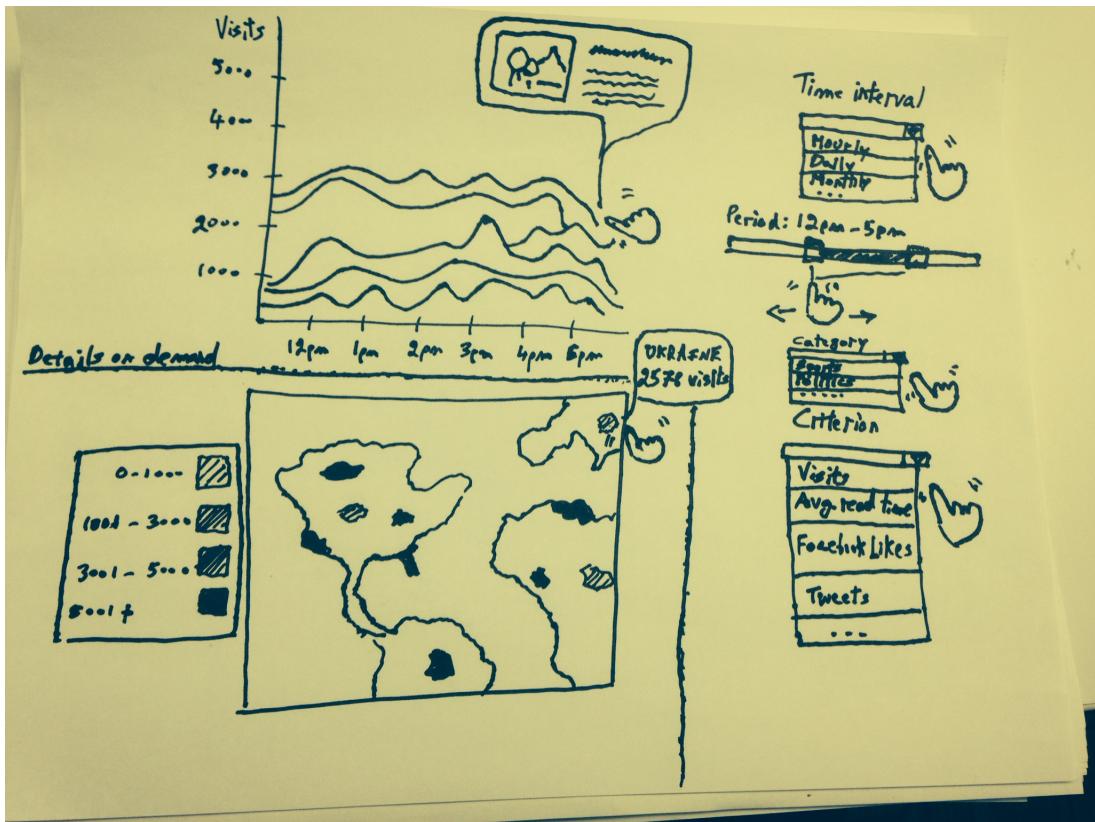

Figure 4 – An initial sketch of what the final artifact was to look like. On the right side reside the controls that allow the user to filter by time interval (daily, monthly, etc.), category (sports, business, politics, etc.), and the output criterion to measure (number of visits, average read time per article, Facebook likes, etc.). The stacked area chart supports hover (details on demand) and click (to navigate to select article). Upon hovering over said article, the map was to highlight the geographic origins of the visitors.

A hand-drawn table on a yellow background. The table has two columns: 'Country' and 'Visits'. The 'Country' column lists USA, Brazil, Spain, Germany, and UK. The 'Visits' column shows horizontal bars representing visit counts. A callout bubble next to the USA row says 'USA 3755 visits'. There are also some handwritten annotations like 'eww!!' and a small drawing of a hand pointing at the USA row.

Country	Visits
USA	3755 visits
Brazil	
Spain	
Germany	
UK	
:	

**Figure 5 – An alternative to the choropleth map in Figure 4.**

I built the system in the following chronological order:

1. Abstracted the web traffic data that needs to be captured and develop the business model. Specifically, I first defined what data was useful and how to develop the algorithms to capture it
2. Built a relational database in MySQL around the results from 1)
3. Developed server-side classes with PHP that captured and retrieved the collected data
4. Researched and experimented with different visualizations that could best fit 2)
5. Developed and implemented the client-side visualization using D3

## 3 Prior Work

### 3.1 Visualization

Prominent researchers in the field of visualization have concocted logical constructs and approaches to designing and implementing visualizations. From a presentation standpoint, there is much emphasis on presenting the end user just enough visual data for the user to achieve the intended task of the visualization. Notions such as expressiveness [1], and increasing the data-to-ink ratio [2] allude to the goal of building visualizations that can be efficiently processed by the human brain. Another desired criterion is effectiveness. Enter the concepts of a domain and task (Munzner [3]). In the design phase, the builder needs to identify the domain that he/she is working with. A domain is a world of ideas and concepts that are abstracted under one umbrella. For example, human anatomy, software engineering are all domains. A domain gives rise to concepts, definitions, and a prebuilt library of shapes and colors by the convention of collective knowledge. For example, red in biology will signify blood whereas in the world of novels it may allude to romance. Knowing the domain aids the designer in introducing artifacts effectively and efficiently. On the other hand, the task refers to the "what" of the visualization. What is/are the goal(s) of the visualization? Is it to explore, analyze, extrapolate, etc.? Clearly identifying the task(s) of the visualization at hand solidifies the direction in which the designer encodes the visual variables (Bertin). Encoding refers to the idea of representing a quantitative or qualitative concept visually. The visual variables include position, size, shape, value, color, orientation, grain, and texture. At this point of the design process, most of the roadmap has been laid out for one to develop design sketches. Perhaps in the pre-Internet days, the implementation would have started here. Though, with the advent of mass computerization and global connectivity, a new ability has been introduced - that of interactivity. Interactivity has been broken down into the following [4]: Overview+Detail, Zooming, Focus+Context, details-on-demand, and cue-based systems.

Time is an essential component to web analytics, as it gives context to what is being measured. Although graphing change over time was attempted in the early A.D.s, the first known contemporary time series graph was published by William Playfair [5]. Playfair was the father of

the line graph and bar graph; it is important to note that during this period visualizing measures over time was not commonplace. Given this, a likely inclination towards visualizing temporal data would have been to plot time against a Cartesian coordinates system. However, there is not a single model that accommodates all domains and tasks [6]. Thus, for the proposed visualization, time must be dealt with in the context of information systems in the news domain.

In order to have a better understanding of the temporal categorization of news, I asked professionals around the news station that I work at for feedback. Based on this and my observations of our news website and other similar entities' websites, "news" refers to a recent occurrence, notably something that happened today. "Breaking News" typically refers to an event that happened within the current day and whose story under development. "Recent News" pertains to stories created within the last 1-3 days. As time approaches the coming year, decade, century, and millennium, news are then compiled and shown in representations such as "year/decade/century/millennium in review". However, in order to achieve a meaningful representation in our visualization I must turn attention to the average lifetime of an article on a news website. Surely, a news article is only "news" when it is recent. Later references could be made to an article when it is its "archives" period, but this would be only a temporal slice that would not be sufficient or useful when the task at hand is to have the user navigate based on recent article popularity. Thus, the time units (aka time granularities) that support the task of the proposed visualization should be minutes and hours (for breaking news), and hours and days (for recent news) [8]. Since I have interest in the general range of these units (e.g. 20 users looked at our article in the last minute/hour/etc.), I will need to use a discrete time scale [7]. The output variables connected to time will mainly be number of hits and the average read time spent on an article.

### 3.2 Existing web metrics systems

What I built is novel in that there is no current navigable and exploratory tool that visualizes near real-time traffic on news sites. Here are a few systems that I found which deal with visualizing web metrics:

## Flow (<http://www.webresourcesdepot.com/beautiful-free-website-traffic-visualization-application-flow/>)

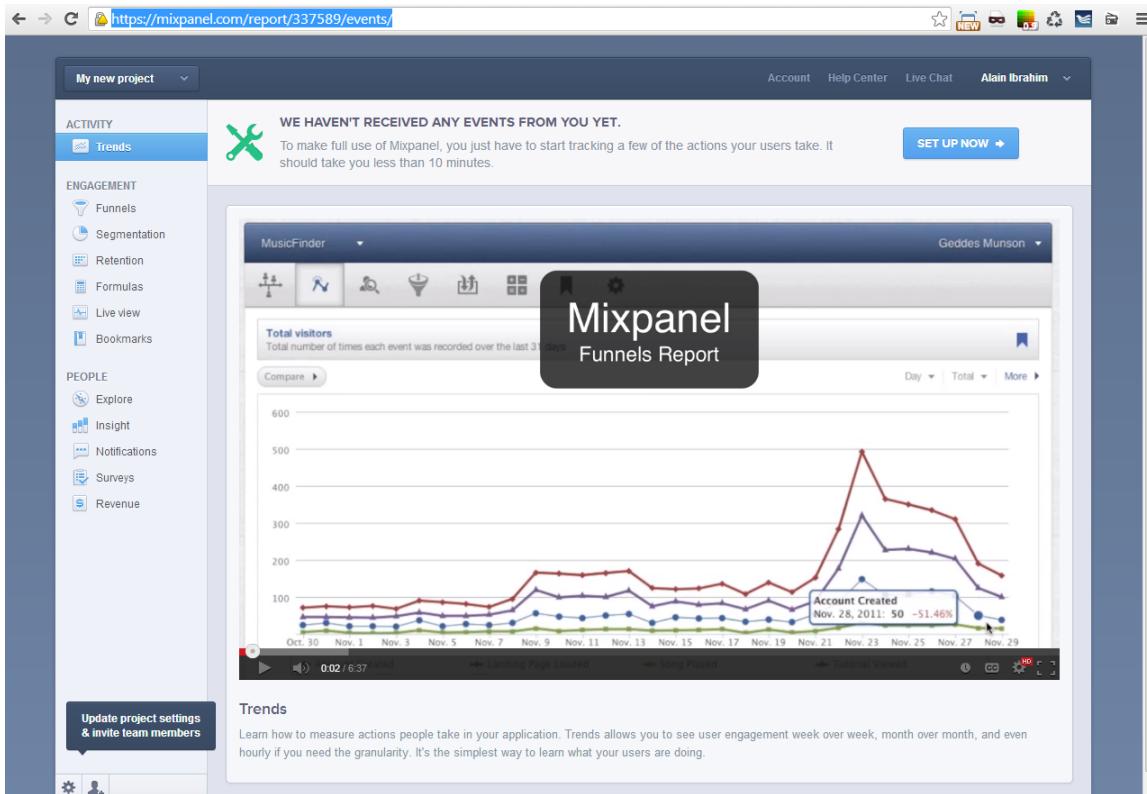

Figure 6 – Shows a line graph that measures the number of hits on the y axis, and date on the x axis for select categories on a given website.

While this can be useful in providing some feedback to the news site's administrators, it does not provide detailed insight to the articles in a given news site. The below screenshot demonstrates another visualization part of Flow.

In order to understand how your website is being consumed and to improve it, **analyzing how users browse the website and which paths they follow is so important.**

Although popular analytics apps like Google Analytics provide this information, [Flow](#) differentiates itself by focusing only to the visualization of paths, displaying **real-time data** and offering all of this with a slick, **impressive and intuitive interface**.

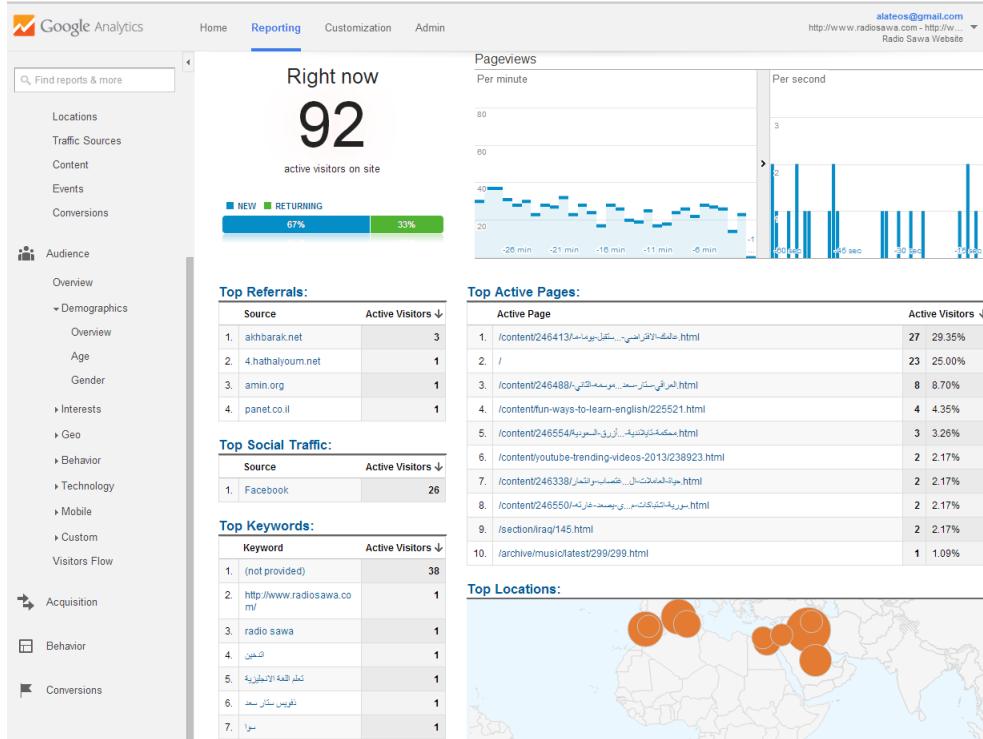

Rather than a chart, it **displays a diagram of the actual paths** people take when they browse your site and you can easily drill-down by clicking each item.

Also, it **presents the number of people leaving from each page** which is a great feedback to find out if those pages require improvements or not.

**Figure 7**

## Google Analytics

**Figure 8 – shows the Real-Time metrics pane in Google Analytics.**

Google Analytics comes in handy in aggregating data and conveying statistical data to the end user. The end user here would navigate here with the intention of running an analysis, such as: From what parts of the world is most of this website's traffic coming from? What links are being most visited? While this is a great tool for management, it is unlikely that the end users will wake up to their coffee looking at this, and then navigating to the actual news website.

## Adobe Analytics

### What is Adobe Analytics?

Adobe Analytics helps you create a holistic view of your business by turning customer interactions into actionable insights. With intuitive and interactive dashboards and reports, you can sift, sort, and share real-time information to provide insights you can use to identify problems and opportunities.

[Download the solution overview > PDF](#)

### Adobe Analytics capabilities.

#### Marketing reports and analytics

Make use of advanced analytics with real-time reporting, powerful visualizations, and dashboards that arm you with the insights you need to guide your business.

#### Ad hoc analysis

Discover a comprehensive, multidimensional view of customer segments that you can use to make accurate, timely, and insightful decisions and improve performance.

#### Data workbench

Measure, analyze, and optimize integrated data from online and offline marketing channels, from high-level trends down to individual customer behavior — all in one place.

#### Predictive analytics

Easily analyze customer data and segment audiences to predict the success of your campaigns and maximize the impact of your ad spend.

#### Real-time web analytics

Access second-to-second analytics reports and real-time tools that allow you to react instantly to visitor trends.

#### Mobile analytics

Dive deep into the performance of your mobile campaigns. Understand how your mobile customers uniquely engage your brand.

Adobe Analytics covers a slew of reporting capabilities:

- **Marketing reports and analytics.** Includes dashboards and reports, conveying key performance indicators, showing marketing strategies' performance in real-time, and displaying the results of ad campaigns
- **Ad hoc analysis.** Includes multidimensional site analysis and advanced reporting
- **Data workbench.** Involves collecting, processing, analyzing, and visualizing Big Data from online and offline customer interactions
- **Predictive analysis.** Pertains to discovering hidden customer behavior

- **Real-time web analytics.** Shows what is happening on the digital properties in real-time so that managers can take action where needed

Once again, the intended audience is that of management and decision makers. What I plan to create is something that the news consumers could see and use to make decisions on what to navigate to.

## 4 Implementation - data capture

### 4.1 Capturing Data

#### 4.1.1 IP Addresses

I captured the IP addresses of the visitors to the subject news site. In PHP, an associative array called `$_SERVER` contains several variables that pertain to the HTTP connection between the client and the server. The variable that contains the IP address from which the user is viewing a select page is called `REMOTE_ADDR`. In code, I registered the visiting IP address like so:

```
$user_ip = $_SERVER["REMOTE_ADDR"];
```

Here, I would like to shed light on the difference between static and dynamic IP addresses. The former is set by the network administrator and is fixed unless it is changed manually. The latter is assigned by the network router, and is assigned for a temporary period called the DHCP lease time. In order to find out the average DHCP lease time set by Internet Service Providers (ISPs), I asked a few network engineers and contacted 3 prominent ISPs (Internet Service Providers). Here are the results:

Network Engineer 1	7 days
Network Engineer 2	3 days
Network Engineer 3	3 days
Verizon (ISP)	14 days
Comcast (ISP)	4-7 days

The average DHCP lease time is between 3 and 7 days. In capturing hits, the threshold of the time limit where a new visit would be counted as a new one practically ranges from seconds to hours. For this reason, I can hold the distinction between static and dynamic IP addresses as constant - as the time revisit threshold is less than the average renew period of at least 1 day. This is important when defining a hit is mainly based on a visit from a unique IP address. The IP address is the only means to track a user and that does not require user authentication.

As for user integrity, one cannot fully ensure that a physical human is sitting behind an IP address when automated scripts may be hitting the IP address of a given news article. Though, my goal is to minimize the inaccuracy when a visitor reaches a news article. I countered this by registering the visiting IP address as soon as the user has moved his/her mouse, or, when he/she has scrolled at least once when viewing the article at hand. I first tested a stub for this successfully in **register\_ip.php**. Here, I have a page containing several blocks of repeated Lorem ipsum text. I used JavaScript to listen to the mousemove and scroll events. I used jQuery to shorthand the event bindings. Below is the code:

```
mouse_moved = false;
page_scroll_counter = 0;

$("body").on("mousemove", function (){
    if (!mouse_moved) {
        \\ Here, a flag would be sent to the server via AJAX
        console.log("Mouse has moved");
        mouse_moved = true;
    } else {
    }
});

$(document).on("scroll", function (){
    if (page_scroll_counter == 1) {
        \\ Here a flag would be sent to the server via AJAX
        console.log("Page has been scrolled")
    } else {
        page_scroll_counter++
    }
});
```

#### 4.1.2 Geographic origins

Another metrics that I captured was the user geographic distribution for a select news article. This required two steps:

1. Capturing the IP address of the user. This was demonstrated in the previous section
2. Obtaining the corresponding latitude and longitude coordinates associated with the user's IP address

Here, it is important to note that many users may be sitting behind HTTP proxy servers. HTTP proxy servers are physical computers/servers that act as proxy points for the client computers. For example, if someone in Russia used a proxy server in the US to visit my news article, the requesting IP address that will be captured will be that of the US - making it appear that the user that visited the article actually came from the US. In PHP, in addition to `$_SERVER["REMOTE_ADDR"]`, there is another variable called `$_SERVER["HTTP_X_FORWARDED_FOR"]`. While the former gets the IP address of the direct requester, the latter gets the originating IP that is making the request. So for example, if I were to be sitting behind an IP proxy server which had an address of 111.111.111.111, then `$_SERVER["REMOTE_ADDR"]` would carry that value.

`$_SERVER["HTTP_X_FORWARDED_FOR"]` would then contain the value of my router's outside IP address - which is what I am looking to map geographically.

If on the other hand the user was browsing the Internet without the use of a proxy server, then `$_SERVER["REMOTE_ADDR"]` would carry the value of the user's router's IP address - reflective of the user's geography. Here is the methodology that used to capture the needed IP address for the geographic lookup:

1. Get the value of `$_SERVER["REMOTE_ADDR"]` and look up its value with a geolocation API. Call this **X**
2. Get the value of `$_SERVER["HTTP_X_FORWARDED_FOR"]` and look up its value with a geolocation API. Call this value **Y**
3. If X and Y are both available, it means that the user is sitting behind a proxy and that the needed IP address is that of Y. If X is available

but Y is not, it means that Y is a private IP address, that of the device behind its router - and thus not behind a proxy server. In this case, X would hold the IP address of the origin.

The next step here is to find a service that would map a given IP address to its corresponding geo coordinates, and ideally to its country name. A quick Google search revealed a convenient REST API service that would output the responses in JSON. **Telize** ([www.telize.com](http://www.telize.com)) is a REST API that allows one to get the visitor IP address and to query the location information for that IP address. The upside of this service is that at the moment it contains no rate limits; thus, one could make an indefinite amount of calls to the Telize API. I was able to test the above clause 3 in PHP code with success. Regardless, of whether I was sitting behind a proxy server or not, the output showed the United States as the country of origin, which means that my code worked.

#### 4.1.3 Average Read Time

One metric that I was curious in attaining was how long the average user spends reading a certain news article. At the moment, a cousin measure called the bounce rate checks to see whether the user continues to browse other pages in the site, or whether the user 'bounces' off to other websites. I find this measure to not be indicative of the level of interest the reader has for a given news article. I plan to quantify the interest level by doing the following:

1. Research the average reading speed of adults that can read English
2. Count the number of words in a given news article
3. Based on the average read speed, calculate the time spent on the news article. If the page is kept open indefinitely by the reader, I will simply use the maximum expected read time for that article. While this is not 100% accurate, it will be highly reflective of the level of interest with the visited articles.

Based on an ophthalmology study that consisted of 50 native English-speaking individuals (average age  $30.38 \pm 9.44$  years; 16 university students, 18 academics, and 16 non-academics) – the average reading speed came out to be  $201.53 \pm 35.88$  words per minute(wpm) for short sentences,

and  $215.01 \pm 30.37$  wpm for long paragraphs [9]. For the scope of this project, I will use the average of 200 wpm to calculate the maximum average time spent on a news article.

## 4.2 Database Design

### 4.2.1 Data Storage

Based on the data that needed to be captured, the below fields were created:

- **Visitor IP address:** Stores the IP address of the visitor reading the news article. In order to avoid capturing page refreshes as new sessions, I will set a threshold of 10 minutes - whereby the server checks if the visitor has visited the article in the past 10 minutes
- **Time Visited:** Stores a timestamp (in GMT) of when the user visited
- **Timezone:** Helpful in determining time differences from GMT
- **Country:** Stores the name of the country where the visitor is from
- **Region:** Stores the region pertinent to the area within the country where the visitor is from
- **Read Time:** Stores the time taken for the reader to have finished reading the article. This should be calculated in seconds
- **Expected Read Time:** Stores the maximum time it should have taken the reader to finish the words in the body of the article
- **Article ID:** Stores the unique identifier and is captured from the host's CMS. This way, future references could be made easily without having to go through mapping algorithms
- **Article Publish Date:** Stores the timestamp of when the article was published
- **Category ID:** Stores the unique identifier of the category, also as it appears in the corresponding CMS
- **Article URL:** Stores the article URL
- **Article title:** Stores the title of the article as it appears in the CMS or on the news site
- **Sample text:** Stores an excerpt of the text from the body of article
- **Sample picture:** Stores a URL to the thumbnail picture of the article

#### 4.2.2 Database Tables

I adhered to the principles of relational database normalization in order to maximize efficiency and eliminate redundancy. For the scope of this project, all the data pertinent to a web hit was stored in a single table:  
**hit (id,ip, time\_visited, *article\_id*, timezone, country, region, read\_time)**

The underline signifies the primary key. The primary key is the field(s) that are enough to determine the rest of the information for any row instance. In this case, the IP address, article ID, and time of visit jointly determine the timezone, country, region, and read time. However, since I need a way to track the user's visits to capture read time, I designated an auto-increment unique identifier called **id**. *article\_id* is italicized since it is a foreign key – that is, it represents a primary key in another table. The time visited is rounded to hour:minute. Therefore, seconds are not accounted for in the visit's time stamp. The read time defaults to the maximum read time as calculated by the article's length. This assumes that the user stayed on the article page indefinitely. In the event that the user does leave the page, this value would then register the actual read time.

The second table needed contained all the metadata pertinent to the visited article:

**article (article\_id, publish\_date, category\_name, article\_url, title, sample\_text, sample\_pic, expected\_read\_time)**

The third table needed contained metadata pertinent to the category of the visited article:

**category (category\_id, category\_name)**

It is important to note here that all of above data is communicated via the server side script which is included in the code of each loaded article.

### 4.2.3 MySQL Database

For this project, I used MySQL since I have good experience with it and for its being open source. MySQL is a relational database management system. Relational databases are those that adhere to relational database design, which relies on the fundamentals of relational algebra and relational calculus. The main tenet of relational design is to maximize efficiency and eliminate any redundancy in the data being stored.

I created a database called **alaini\_news\_viz** on my web host. For this, I created two users:

- **alaini5\_newsread**: This account is solely used to read from the database. Ultimately, it will be used to invoke the visualization by the visitor/end user
- **alaini5\_newsedit**: This account is mainly used to register the IP hits and read times communicated to the server

I created 3 tables in MySQL using phpMyAdmin, an open source PHP based GUI that facilitates interacting with the MySQL system:

#### 1. article

#	Name	Type	Collation	Attributes	Null	Default	Extra
1	article_id	int(11)			No	None	AUTO_INCREMENT
2	category_id	int(11)			No	None	
3	article_url	varchar(150)	latin1_swedish_ci		No	None	
4	title	varchar(150)	utf8_general_ci		No	None	
5	sample_text	text	utf8_general_ci		No	None	
6	sample_pic	varchar(150)	latin1_swedish_ci		No	None	

Check All    With selected:    Browse    Change    Drop    Primary

Print view Propose table structure Move columns

Add 1 column(s) At End of Table At Beginning of Table After

+ Indexes

Information

Space usage		Row statistics	
Data	0 B	Format	dynamic
Index	1 KiB	Collation	latin1_swedish_ci
Total	1 KiB	Rows	0

Data	0 B	Format	dynamic
Index	1 KiB	Collation	latin1_swedish_ci
Total	1 KiB	Rows	0
		Creation	Jun 19, 2014 at 04:15 PM
		Last update	Jun 19, 2014 at 04:15 PM

## 3. hit

The screenshot shows the 'hit' table in MySQL Workbench. The table has eight columns: 'id' (int(11)), 'ip' (varchar(15)), 'time\_visited' (int(15)), 'article\_id' (int(11)), 'timezone' (varchar(30)), 'country' (varchar(80)), 'region' (varchar(80)), and 'read\_time' (int(5)). The 'ip' column uses the latin1\_swedish\_ci collation. The table contains one row with the value '1'. The 'Information' panel displays space usage (0 B Data, 1 KiB Index, 1 KiB Total) and row statistics (Format: dynamic, Collation: latin1\_swedish\_ci, Rows: 0, Next autoindex: 1, Creation: Aug 06, 2014 at 11:17 AM, Last update: Aug 06, 2014 at 11:17 AM).

#	Name	Type	Collation	Attributes	Null	Default	Extra
1	id	int(11)			No	None	AUTO_INCREMENT
2	ip	varchar(15)	latin1_swedish_ci		No	None	
3	time_visited	int(15)			No	None	
4	article_id	int(11)			No	None	
5	timezone	varchar(30)	latin1_swedish_ci		No	None	
6	country	varchar(80)	latin1_swedish_ci		No	None	
7	region	varchar(80)	latin1_swedish_ci		No	None	
8	read_time	int(5)			No	0	

Information:

Space usage		Row statistics

## 4.3 PHP server-side code

### 4.3.1 Configuration and database connection

Here, I created two files:

1. **constants.php**: Holds all the constants that are defined across the application, inclusive of those for the database connection
2. **db\_connect.php**: Performs the PDO database connection based on the given connection parameters

Note that both of these files are stored one directory above **public\_html/** for security reasons. This folder is called **lib/**. Thus, the two files are not accessible directly to the public and accordingly need to be included in other PHP files.

### 4.3.2 Server-side hit, article, and category capture

Each table in my database is represented with a PHP class. Hence, the creation of the following 3 classes:

1. **Hit.php**: This class registers all of the metadata pertinent to a user visit. This data includes IP address, country, region, timezone, and time visited.
2. **Article.php**: This class captures all of the metadata pertinent to the article being visited. Such includes title, text excerpt, thumbnail URL, and article URL.
3. **Category.php**: This class captures any metadata pertinent to the parent category of the visited article. At the moment, I am only capturing the name of the category.

In addition to the above, I have created a helper file that registers the read time of a given article. By default, the read time is registered as 1 second in the database. Once a hit is registered in the database, the id of the newly created hit is then passed to the DOM of the article page. There, the id is used via an AJAX call to store the calculated read time for the visited article in the database. This file is called **updateReadTime.php**.

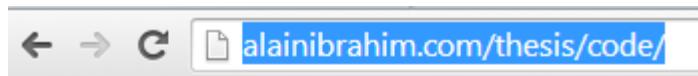

## 4.4 Client-side read time capture with Javascript

As mentioned in the last section, the hit id is passed to the client page in order to keep a way to identify and update the read time for the visited article. Here, I calculate the number of words that are stored in the article. I do this by first getting all of the text found within common article tags - namely `<span>`, `<div>`, `<article>`, `<p>`, and `<section>`. I then sum the number of words found within all of the mentioned tags. I ensure that double counting is avoided by using the `innerText` property; this counts the elements inner text, but not any text that might be included in one of its children nodes. Next, I calculate the number of seconds the article is on average expected to take to read. Based on my earlier research, I will use the average figure of 200 words per minute. This figure is used in the event that a user leaves the page open indefinitely. Thus, if an article should take about 5 minutes to read, and the user takes (for whatever reason) 30 minutes to navigate away from or to close the article, then I simply register the 5 minutes. Although I may be compromising some accuracy here, it is much more advantageous than having instances inflate the read time significantly.

Once the article page loads, and the expected read time calculations have been made, a timer is readied. The timer is triggered once a user moves the mouse or when the user scrolls the page. This minimizes storing metadata created by bots and to a high extent ensures that a human is sitting behind the screen. Upon navigating away from or closing the article, the read time is then submitted to `updateReadTime.php` and eventually recorded in the database. This part of the implementation relies on `window.onbeforeunload` or `window.onunload`, depending on the browser's user agent. At the time of this writing, this method only for Firefox and Chrome.

## 4.5 Tying it all together

Now that both the back end and front end code has been implemented, I was able to move on to testing this system. I created a miniature lorem ipsum page which acts as an article being visited.

Now, here's the content of the page:

```
 Lorem ipsum dolor sit amet, consectetur adipiscing elit. Donec sit amet felis elit. Pellentesque consequat pharetra ante. Donec eu lectus non turpis interdum elementum ac vel diam. Donec molestie feugiat vitae quis felis.
```

In my PHP code, I populated mock metadata for the article and category. The hit metadata, however, was populated based on the visit data. I went ahead and visited the page for 10 seconds and got the following results:

A screenshot of a MySQL database interface showing the results of a query. The query is:

```
SELECT * FROM `hit`
```

The results table has the following data:

	+ Options	id	ip	time_visited	article_id	timezone	country	region	read_time
<input type="checkbox"/>	<a href="#">Edit</a> <a href="#">Copy</a> <a href="#">Delete</a>	1	98.172.153.142	1408462100	1	America/New_York	United States	Maryland	10

Below the table are buttons for "Check All", "With selected:", "Change", "Delete", and "Export". There are also "Number of rows:" dropdown menus at the top and bottom of the table area.

My ip address, time of visit, article id (at this point a fake one), timezone, country, region, and read time were all stored in the **hit** table.

SELECT * FROM `article`					
<input type="checkbox"/> Profiling [ Inline ] [ Edit ] [ Explain SQL ] [ Create ] Number of rows: 25 ▾					
+ Options [ T ] ↴ ↵ article_id category_id article_url title sample_text sample_pic <input type="checkbox"/> Edit <input type="button" value="Copy"/> <input type="button" value="Delete"/> 1   1   http://alainibrahim.com/thesis/code   alain is testing an article   Lorem ipsum dolor sit amet, consectetur adipiscing...   http://alainibrahim.com/thesis <input type="checkbox"/> Check All    With selected: <input type="button" value="Change"/> <input type="button" value="Delete"/> <input type="button" value="Export"/>					
Number of rows: 25 ▾					

The article id, category id, article URL, article title, article sample text, and the URL to the article's main pic - were all stored in table **article**.

SELECT * FROM `category`	
<input type="checkbox"/> Number of rows: 25 ▾	
+ Options [ T ] ↴ ↵ category_id category_name <input type="checkbox"/> Edit <input type="button" value="Copy"/> <input type="button" value="Delete"/> 2   Thesis	

Lastly, the category id and name were both stored in the **category** table.

This concludes the part of the system that implements the data capturing. The next step was to connect this library to a working website. For the scope of this thesis, I implemented the hook to specifically tie into a widely used Content Management System - Wordpress.

## 5 Implementation - hooking into Wordpress

Wordpress calls its articles "posts". The template file for each post is called **single.php** and is found under the current theme that is being used. One can think of a theme as a set of pre-built PHP, HTML, CSS3, and Javascript templates that structurally and visually dictate how the website looks and behaves. Thus, in order to accomplish the task of capturing the data from a certain article, I needed to include my capture library inside **single.php**. However, since my library cannot directly communicate with Wordpress, I had to create a hook that abstracts some of Wordpress's built-in functions. Lastly, I needed to ensure that Wordpress is using jQuery version 2.1.1 or higher. As this is a Javascript library and that I need available as soon as the page loads, I needed to include it in **header.php** - which basically comprises the `<head></head>` portion of a given page. Below is a breakdown of how I hooked into Wordpress.

### 5.1 Creating the captureLib folder

In the interest of portability, I have placed all of my code within a folder called **captureLib**. If a 3rd party wishes to uses this library in the future, all that would be needed is to simply include **captureLib** from within **single.php**. Here is a screenshot of the current directory structure of **captureLib**.

Name	Date modified	Type	Size
lib	9/2/2014 10:17 AM	File folder	
Article.php	8/31/2014 6:26 PM	PHP File	2 KB
captureHit.php	9/11/2014 4:41 PM	PHP File	3 KB
Category.php	8/17/2014 1:35 PM	PHP File	1 KB
countries.php	9/11/2014 10:54 AM	PHP File	4 KB
getReadTimeLibrary.php	9/1/2014 4:38 PM	PHP File	1 KB
Hit.php	9/11/2014 10:56 AM	PHP File	4 KB
readTime.php	9/1/2014 8:30 PM	PHP File	5 KB
updateReadTime.php	9/10/2014 5:34 PM	PHP File	1 KB
wordpressHook.php	9/11/2014 4:40 PM	PHP File	2 KB

Below is a breakdown of the current directory structure of the code that captures hits and read times.

1. **lib/**

- (a) **constants.php** - contains all the server-side constants that will be used to capture the hits
- (b) **db\_connect.php** - connects to the database where the hits are stored

- 2. **Article.php, Hit.php, Category.php** - as mentioned previously, these are abstractions that communicate the data from and to the database
- 3. **getReadTimeLibrary.php** - a line of code to include the read time Javascript code if a hit was registered

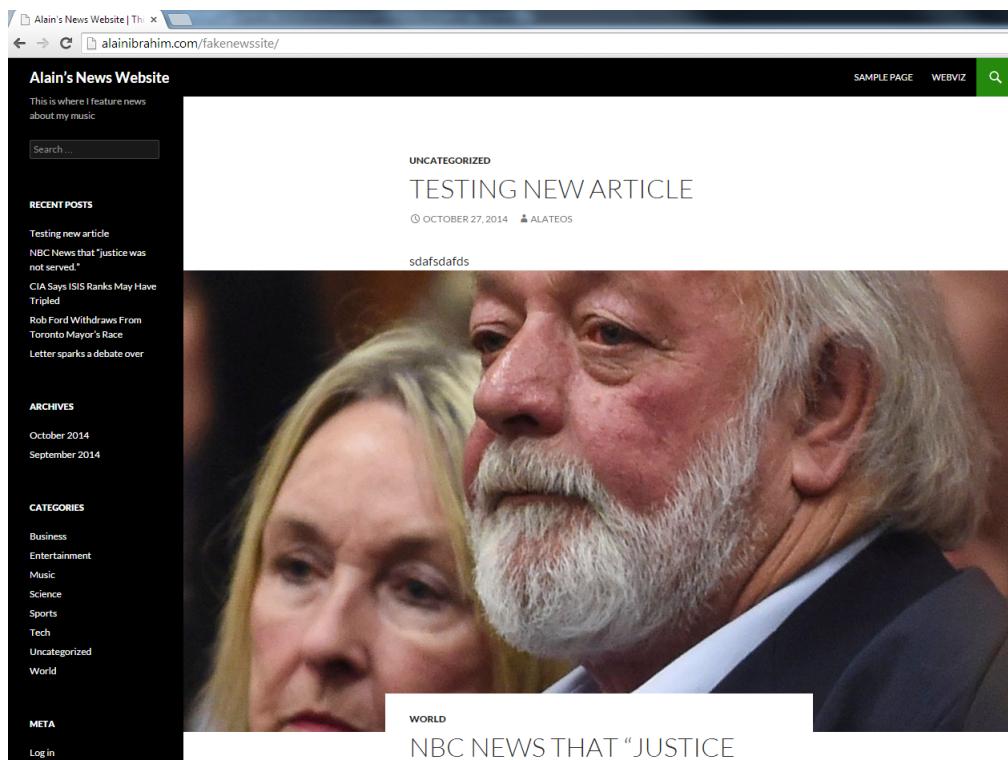

```
<?php
    /**
     * A terse way of including the Javascript library. The library
     * itself is suffixed with .php instead of .js because there is
     * a php variable defined in the actual Javascript library
     */
    if ($hit_id) { include("readTime.php"); }
?>

\item
```

- 4. **readTime.php** - this is the Javascript code that captures the read time. It is suffixed with .php (vs. .js) since it requires PHP code to output the hit id within the Javascript. I have made adjustments to this code to accommodate for users switching tabs while reading a certain article. When the article's window loses focus, the timer stops counting; it only resumes when the user gets back to the article window. This maximizes accuracy in the average read time readings.
- 5. **wordpressHook.php** - as mentioned earlier, this is an abstraction into Wordpress's needed built-in functions. In order to hook to different CMSs, the code can be reused. All that would be needed to change is the implementation.
- 6. **countries.php** - contains an array that has all country names. Used for database seeding.

## 5.2 Creating a mock news website

In order to test the library, I created a mock news site in Wordpress. In this setup, I built the following categories: Business, Entertainment, Music, Science, Sports, Tech, and World. I tasked a friend to populate mock articles with content that is fitting to the parent category. I created the Wordpress install under my personal web hosting account. The URL to it is <http://www.alainibrahim.com/fakenewssite>. In the interest of time, I used the default theme that came out of the box.

## 5.3 Testing

### 5.3.1 Proof of concept

Below is the result of my having visited 3 different articles, each for a different amount of time:

category_id	category_name
8	Music
7	Entertainment
5	Tech
6	Science

In the **category** table, the categories metadata of the different articles that I visited were stored in the database. Note that if say I visit an article of the same category again, the category will not be double stored.

article_id	category_id	article_url	title	sample_text	sample_pic
16	8	http://alainibrahim.com/fakenewssite/?p=16	I like dance music	EurodanceÃ (sometimes known asÃ Euro-NRG, or other...	none
10	7	http://alainibrahim.com/fakenewssite/?p=10	Testing lorem ipsum	Lorem ipsum dolor sit amet, consectetur adipiscin...	http://alainibrahim.com/fakenewssite/wp-content/up...
8	5	http://alainibrahim.com/fakenewssite/?p=8	Alain's second post	This is a paragraph This is another paragraph	none
6	6	http://alainibrahim.com/fakenewssite/?p=6	Alain's first post	This is Alain testing the first post blah bla blah	none

In the **article** table, the articles' metadata was stored. The sample text is excerpted by PHP with a default setting of 500 characters.

id	ip	time_visited	article_id	timezone	country	region	read_time
1	98.172.153.142	1409674585	16	America/New_York	United States	Maryland	6
2	98.172.153.142	1409674593	10	America/New_York	United States	Maryland	8
3	98.172.153.142	1409674603	8	America/New_York	United States	Maryland	2
4	98.172.153.142	1409674611	6	America/New_York	United States	Maryland	3

The read times appear to have registered successfully in the **hit** table.

### 5.3.2 Seeding mock data

After testing the capture of data successfully, I needed a way to mimic traffic on a real news website. In addition, I needed to make it appear as if each mock article visit came from a random country of origin. Below are the steps I took to accomplish this:

1. Modified **constants.php** to include a flag that denotes whether the app is in test or production mode:

```
...
// defines whether we are in test or production mode
define('PRODUCTION_ENV', false);
```

2. Modified class **Hit.php** to produce a fake read time and fake US state of origin if in test mode:

```
...
// if in test environment, populate fake data for read time and country of origin
if (!PRODUCTION_ENV) {
    // get a random time between 10 seconds and 3 minutes
    $read_time = rand(10,180);

    // get the list of all the states in the US, and pick one randomly
    include("states.php");
    $region = $states[array_rand($states)];
}
...
```

3. Created **makeFakeHit.php** to invoke a visit to a random article on my fake news site:

```
/**
 * The sole purpose of this file is to visit a random article on the
 * fake news site, causing hits to register
 */
$TESTING_IP = "98.172.153.142";

// 290 is the id of the last fake article that was created
$article_id = rand(1,290);

// cause a fake visit only if testing ip address is registered here
if( $_SERVER['REMOTE_ADDR'] == $TESTING_IP ) {
    file_get_contents("http://alainibrahim.com/fakenewssite/?p=" . $article_id );
}
```

Note that I have hard coded a testing IP address so that I am the only person who can run this for testing.

4. Created **fakeVisit.html** to run on the client side and to call **makeFakeHit.php** at a pre-specified time interval(using Javascript):

```
(function () {
    // the amount of time to wait before revisiting the site (in seconds)
    var REVISIT_INTERVAL = 20;

    // trigger the fake visit on the server side
    var makeFakeHit = function () {
        $.get("makeFakeHit.php");
    }

    // set a recurrent loop to seed the data
    setInterval(function () {makeFakeHit(); console.log("hit issued")}, (REVISIT_INTERVAL*1000));
})()
```

Below is a snapshot of the results of the seeding of the database:

<b>id</b>	<b>ip</b>	<b>time_visited</b>	<b>article_id</b>	<b>timezone</b>	<b>country</b>	<b>region</b>	<b>read_time</b>
15	198.46.91.105	1412719610	242	America/Los_Angeles	United States	Wisconsin	30
14	198.46.91.105	1412719268	248	America/Los_Angeles	United States	Washington	60
13	198.46.91.105	1412719230	252	America/Los_Angeles	United States	Utah	150
12	198.46.91.105	1412719208	214	America/Los_Angeles	United States	Mississippi	146
11	198.46.91.105	1412719188	252	America/Los_Angeles	United States	Ohio	60
10	198.46.91.105	1412719129	211	America/Los_Angeles	United States	Connecticut	45
9	198.46.91.105	1412719111	109	America/Los_Angeles	United States	Vermont	17
8	198.46.91.105	1412719068	209	America/Los_Angeles	United States	Alabama	54
7	198.46.91.105	1412719049	217	America/Los_Angeles	United States	District of Columbia	60
6	198.46.91.105	1412718849	287	America/Los_Angeles	United States	Colorado	168
5	198.46.91.105	1412718788	290	America/Los_Angeles	United States	Wisconsin	34
4	198.46.91.105	1412718770	214	America/Los_Angeles	United States	Delaware	12
3	198.46.91.105	1412718631	26	America/Los_Angeles	United States	Oregon	134
2	198.46.91.105	1412718388	216	America/Los_Angeles	United States	Maine	62
1	198.46.91.105	1412718288	26	America/Los_Angeles	United States	Georgia	52

Note that for each hit, the data that is generated by the seeding process is **article\_id**, **region**, and **read\_time**. The other values were left as is because for the scope of this project, they will not be factored into the final visualization.

## 6 Implementation - retrieving captured metrics

At this point, the database was populated with a good amount of data and I needed a way to retrieve it. For this, I created a folder on the server side and called it "vizLib". In this directory I created 3 PHP files that will output results in JSON:

1. **getCategories.php** - outputs all the used article categories.
2. **getCategoriesMetrics.php** - outputs all of the metrics for all categories.
3. **getArticlesMetrics.php** - outputs all of the metrics for all the articles given a category ID, beginning visit time, and ending visit time.
4. **getArticleCountriesMetrics.php** - outputs all of the country metrics for a given article ID.
5. **index.php** - the landing page for the visualization

## 7 Implementation - visualization

For the visualization, I enabled the following tasks for the users:

- To compare articles' hits and reader attention spans for any period within the last month, given a select category
- To preview each article's thumbnail, title, and excerpt
- To contrast the geographic distribution of hits and attention of up to 2 articles
- To navigate to the full article counterpart on the subject news website

### 7.1 The controls box

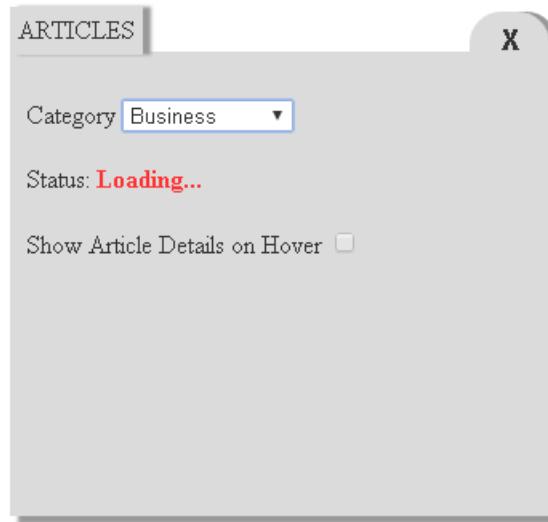

Typically, controls take up space in the limited real estate area available in any web browser. I decided to have the controls be draggable and minimizeable so they don't negatively impact the user experience.

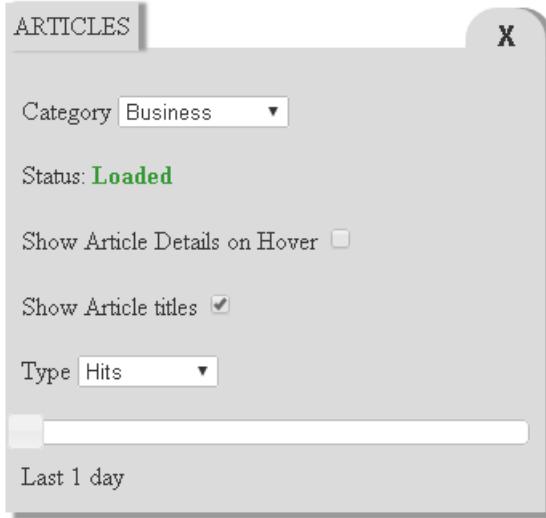

The controls box first partially loads when no category is selected. The "X" hides it; when this is done, the top left gray rectangle with the two white dots is then contoured by a black border - to indicate that it is hidden.

Upon loading the visualization, an AJAX call is made to the server which fetches all the news categories into this dropdown box. Once a category is selected, a call is made to the server, which results in all of the data for the selected category to be fetched from the database using the server-side script. The user is notified (via the red colored "Loading..." indicator) of when the data is being loaded:

[ . ]

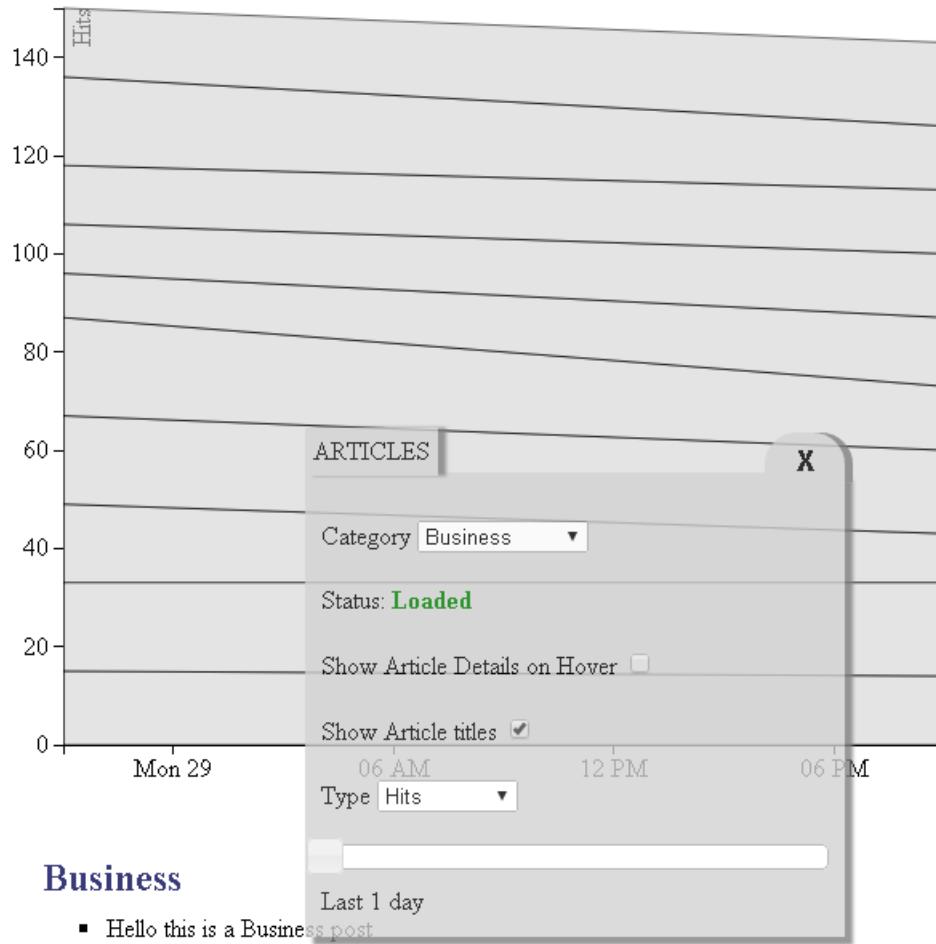

And, once the data is loaded, the status label turns green and reads "Loaded":

Below are the descriptions for each component of the controls area:

- **Category** - sets the category whose articles the user chooses to see
- **Status** - shows the data transfer status of the selected news category
- **Show Article Details on Hover** - determines whether a preview of the article will pop up upon hovering over an article in the stacked area chart.
- **Show Article titles** - toggles the visibility of the article titles in the bottom portion of the screen
- **Type** - the user gets to select between viewing the number of hits or amount of time spent (in seconds) on the Y axis of the stacked area chart
- **Time slider** - This is a dual time slider control in that the user can use it to select one slice (i.e. day) in time or can alternatively select a time range to view the data in

I made the controls box transparent in case the user wants to keep it afloat the visualization:

## Business

- Hello this is a Business post
- Dollars VS People?
- Top Obama Officials Disagree Over Whether U.S. At War With ISIS
- \$3 Per Gallon Gas, Here We Come
- Are you putting food on your table?
- Madoff Son Andrew Wills More Than \$15 Million to His Fiancée and Family
- Do you have a profile with ISIS?
- PhD dropout? Lucrative Silicon Valley career
- Facebook Tests Disappearing Posts Feature
- August PS4 and Xbox One Sales Continue to Break Records

## 7.2 Stacked area chart

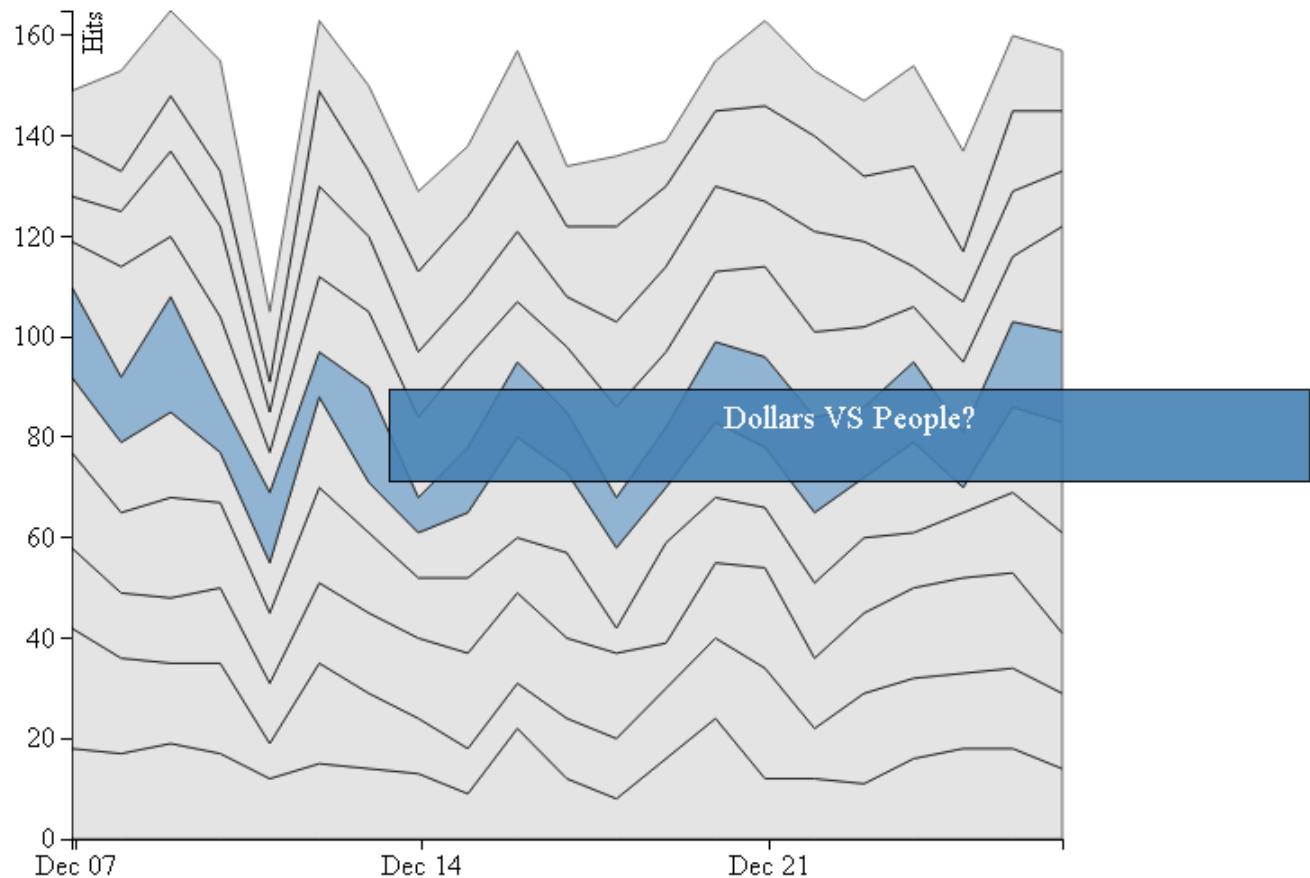

Here, the goal was to create a visual product that would allow the user to view all the articles' popularity over time, given a certain news category. I knew that I wanted time to go on the horizontal X axis, and (hits or read time) to go on the Y axis. That said, I first started with a simple line graph, where each line represented an article that was colored differently from the other lines. There were 2 downsides which led me to abandon the line graph:

- The lines intersected into a spaghetti mash-up, making it very difficult to spot any significant patterns
- When a category (e.g. Business) contained more than say 10 articles, I had to use 10 different colors to encode the articles. The issue here was that at a certain point, colors became very similar making it almost impossible to visually query the article all the way through a selected time period

I instead used the stacked area chart. The stacked area chart maintained a view on the patterns without compromising legibility and supports the following tasks:

- To compare articles' hits and reader attention spans for any period within the last month, given a select category
- To preview an article's thumbnail, title, and excerpt

The X axis is laid out using D3 and represents a time aggregation that occurs on an hourly basis.

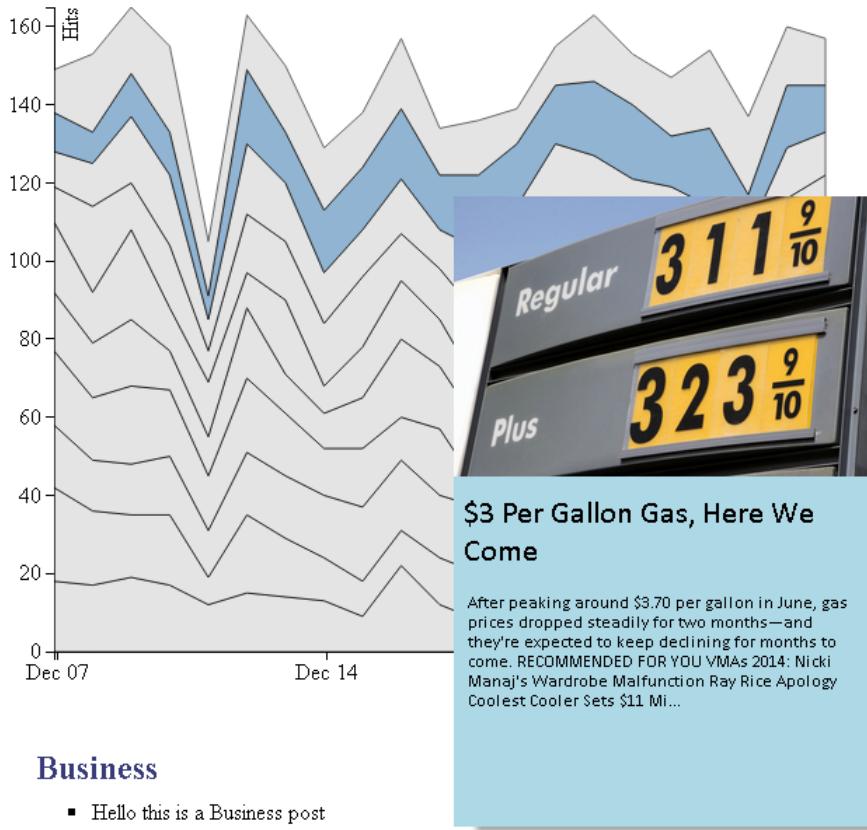

## Business

- Hello this is a Business post
- \$3 Per Gallon Gas, Here We Come
- August PS4 and Xbox One Sales Continue to Break Records
- Facebook Tests Disappearing Posts Feature
- **Dollars VS People?**
- Top Obama Officials Disagree Over Whether U.S. At War With ISIS
- Madoff Son Andrew Wills More Than \$15 Million to His Fiancée and Family
- Do you have a profile with ISIS?
- PhD dropout? Lucrative Silicon Valley career
- Are you putting food on your table?

The articles are stacked vertically, each respectively matching its title in the below white space area, which is headed by the selected category. The readying of the data for the stack is done using the D3 area layout, and the visual representation is implemented by using the SVG <path>. The paths by default all contain a fill of light gray.

Hovering over any article in the stack chart causes both the article's area and corresponding title to turn to steel blue. In reverse, hovering over an article title in the bottom area causes the corresponding article's area in the stack chart to have a fill color of steel blue. It is important to note that the user has the option to see a preview of the selected article when checking "Show Article Details On Hover" in the controls box:

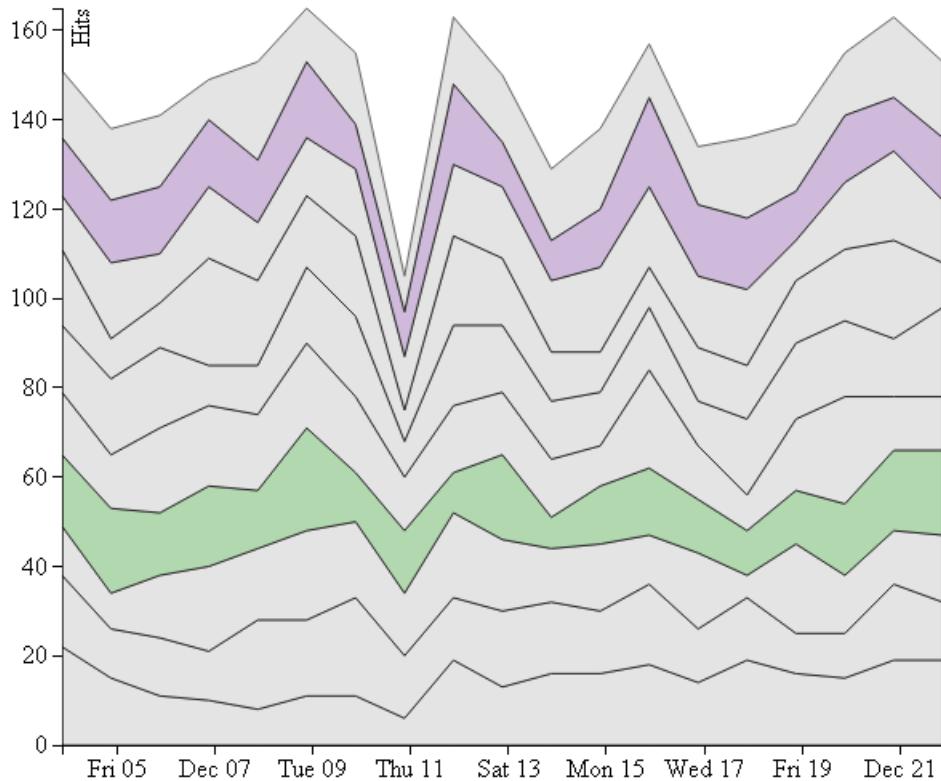

## Business

- Hello this is a Business post
- **\$3 Per Gallon Gas, Here We Come**
- August PS4 and Xbox One Sales Continue to Break Records
- Facebook Tests Disappearing Posts Feature
- Dollars VS People?
- Top Obama Officials Disagree Over Whether U.S. At War With ISIS
- Madoff Son Andrew Wills More Than \$15 Million to His Fiancée and Family
- Do you have a profile with ISIS?
- PhD dropout? Lucrative Silicon Valley career
- Are you putting food on your table?

This results in an overlay to pop over the selected article that includes the article's thumbnail, title, and a 500-character excerpt of the body of the article.

The user is given the option to contrast the pattern of up 2 articles over time, by left clicking on the select article area. This results in one article being filled with a purple color and the other with a green color. I picked the colors from colorbrewer2.org and ensured they were colorblind safe.

Once the two articles are selected, their corresponding geographic distributions are shown in the right area of the browser. This is covered in the next section.

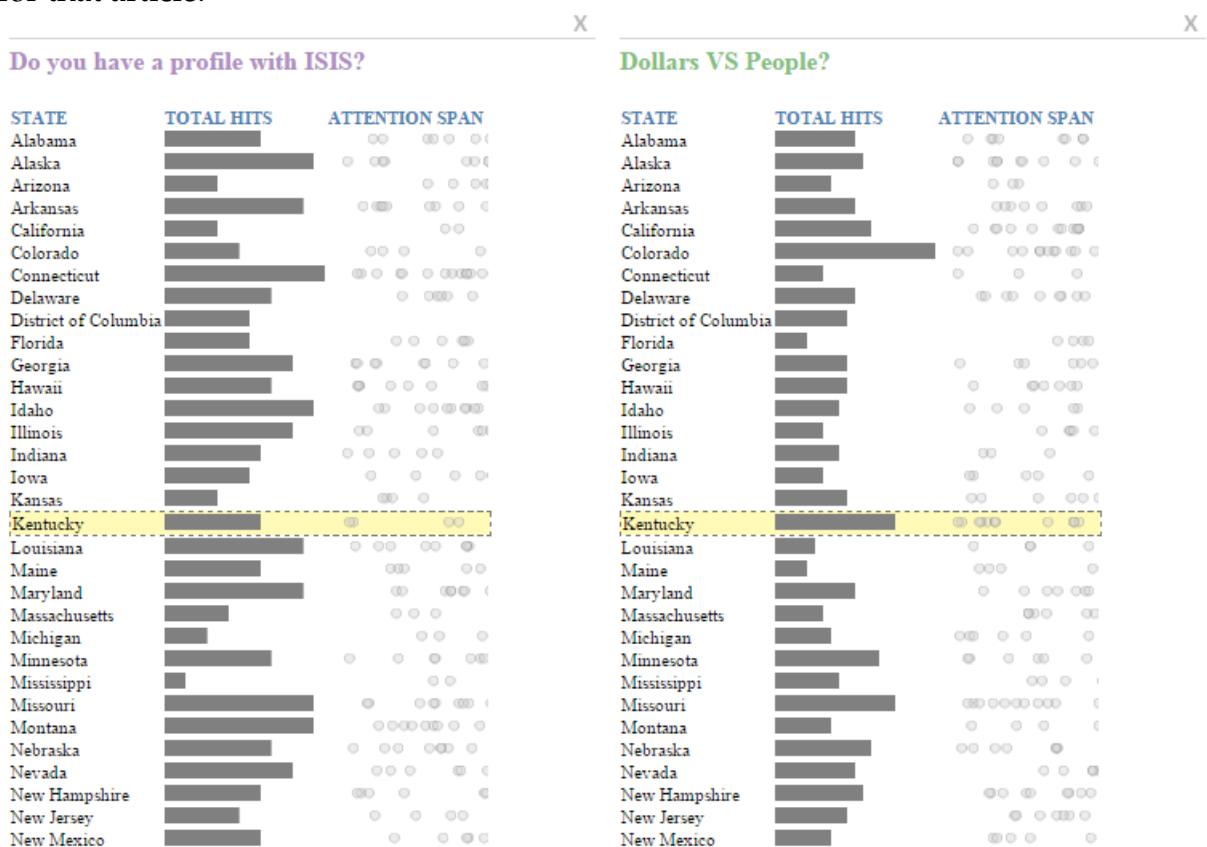

## 7.3 Geographic bar charts

In the previous section, two articles are clicked on in the stacked area chart. In addition to their being highlighted in the stacked area chart, a right side pane populates each article's title in its color, along with a table below it. The table contains the geographic origin (e.g. state/country), the total number of hits, and the attention span distribution (i.e. read time in seconds).

Whenever a first article is selected, the second article is compared along the same geographic areas for uniformity. That is, only the geographic areas that were included in the first article were displayed for the second article. Clicking the top right "X" removes the article from the right pane, and renders the graph area counterpart back to light gray. The hits values are encoded as horizontal bars in dark gray. The attention span column contains a distribution of the captured read times, represented as light

gray circles; the amount of seconds spent is encoded by the horizontal position of each circle. The circles are transparent to allow for overlap. The maximum horizontal position of the circle is demarcated by the expected read time. The expected number of seconds was discussed earlier, and is a measure that takes into account the average adult human reading speed and the number of words contained within the article. The total hits bar spans relative to the highest hits value for that article - meaning, the bar that takes up the biggest width is the highest hit value that was registered for that article.

We now examine the geographic area in more detail. Note that automatically, the entries are sorted by the name of the geographic origin, in ascending order. Clicking on the "STATE" header will toggle back and forth the sorting order of the geographic origin name. Similarly, toggling the "TOTAL HITS" header will sort the data in ascending/descending order. When the data is sorted, it is sorted according to the same criterion for

both articles. Hovering over a row will cause that row to be highlighted in yellow, and to be contoured in a dashed line solid border. Hovering over any bar will in addition pop up a steel blue overlay which displays - using white text - the number of hits or read time in seconds.

The geographic bar charts support the following tasks:

- To contrast the geographic distribution of hits and attention of up to 2 articles
- To navigate to the full article counterpart on the subject news website

## 8 Results

### 8.1 Mock Website

The working example that I have discussed so far is based on a mock website that I created using mock visit data.

#### 8.1.1 Capturing Web Metrics

- For each hit, the following metadata was successfully captured: IP address, time visited, article ID, time zone, country of origin, and region of origin
- For each hit, the read time was captured as a random number between 10 and 180 seconds. When I switched the flag in my PHP code to denote the production environment, the read time was captured successfully when I navigated away from a news article. Most of my testing was done in Google Chrome version 39
- Each hit was captured according to the revisit threshold time (in seconds) that was specified in the PHP code
- Each category was captured from Wordpress via the PHP libraries I created
- Each article's metadata was captured from Wordpress via the PHP libraries I created

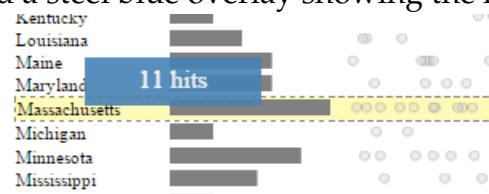

#### 8.1.2 Retrieving Web Metrics

- The categories were successfully retrieved in JSON via `getCategories.php`
- The hits data was retrieved successfully from the MySQL database using JSON via `getArticlesMetrics.php`. I initially reserved the geographic data for the articles to be serviced by `getArticleStatesMetrics.php`. However, I felt that in a production environment that many SQL calls to the database server would slow down the system and affect all users. In order to minimize the number of requests to the server, I had the server fetch all data for a given category for the

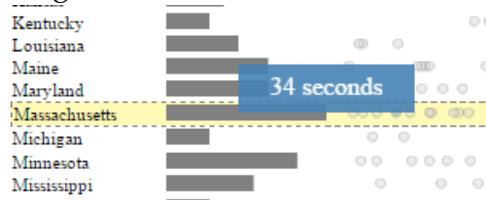

last 31 days. The client-side Javascript code then parsed and re-organized the fetched data to be used by the interactive visualization

### 8.1.3 The Interactive Visualization

- The final product included a stacked area chart, a list of article titles, and a right pane for geographic analysis of up to 2 articles
- The hits were first aggregated on a minute to minute basis. Though, this resulted in performance degradation. Adjusting the date range took a delay of about 2-3 seconds to reflect in the redraw of the stacked area chart. I then aggregated on an hourly basis, which ended up plotting Y values over 744 (31 days x 24 hours) X axis time values. This eliminated the delay in the stacked area chart redraw
- The stacked chart accurately reflected the number of hits and average read time over the selected time range
- Clicking one or more articles highlighted the article area in the stacked area chart and displayed the total hits based on geography. It also showed the distribution of the recorded read times. For the mock site, the geography was limited to states within the United States
- The tables that contained the geographic origins were sortable by total hits and by state name - in ascending and descending order
- When "Show Article Details on Hover" was enabled, the pertinent article's thumbnail image, title, and body excerpt were successfully presented in an overlay
- Hovering over any row in the geographic hits and attention span table resulted in the row being highlighted in yellow for all articles that are being compared
- Hovering over a bar representation of the total number of hits invoked a steel blue overlay showing the number of hits

- Hovering over an attention span circle invoked a steel blue overlay showing the number of seconds that was spent on the article

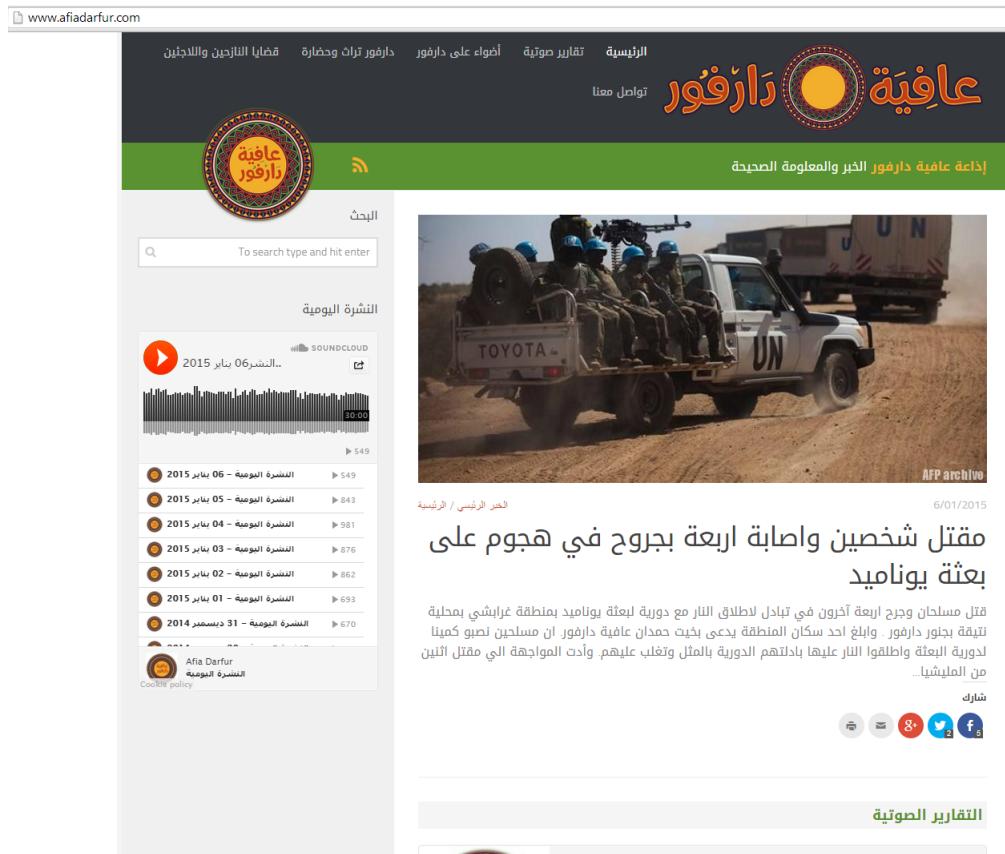

#### 8.1.4 Performance

- In the mock site, the last 31 days amounted to 4500 hits per category. The time it took for them to be loaded in the visualization was around 4 seconds, using a PC with an Intel i7 processor and 12 GB of RAM
- When changing the date range, the stacked chart's redraw time was almost instantaneous. Again, using a PC with an Intel i7 processor and 12 GB of RAM
- When "Show Article Details on Hover" was enabled, there was a delay of about 500 milliseconds for the image thumbnails to initially show. Once they were cached in the browser's memory, they appeared without delay. For images that were not cached, the delay was about 1 second per megabyte in picture size

## 8.2 Actual Website

Being a web developer at a news organization, I was able to test the system against one of our mini sites - Afia Darfur (<http://www.afiadarfur.com>), since it was using Wordpress as the back-end platform. The site targets people in Sudan and keeps them up to date with news specific to Sudan.

### 8.2.1 Hooking the Custom Libraries into Afia Darfur

Hooking into the live website involved the following steps:

1. Creating a database for the web metrics
2. Placing the `captureLib/` folder in the root folder of the Wordpress theme

3. Including the capture library in Wordpress's **single.php**
4. Including the **vizLib/** folder in the root directory of the website
5. Placing **updateExpectedReadTime.php** and **updateReadTime.php** in the root directory of the website

### 8.2.2 Capturing Web Metrics

- For each hit, the following metadata was successfully captured: IP address, time visited, article ID, time zone, country of origin, and region of origin
- The read time was captured successfully when I navigated away from a news article. Most of my testing was done in Google Chrome version 39
- Each hit was captured according to the revisit threshold time (in seconds) that was specified in the PHP code. For Afia Darfur, this was set to 20 seconds
- Each category was captured from Wordpress via the PHP libraries I created
- Each article's metadata was captured from Wordpress via the PHP libraries I created. In order to ensure that the Arabic text was captured, I had to change the collation of the database tables to utf8\_general\_ci
- The PHP library files responsible for capturing data had to be encoded in UTF-8

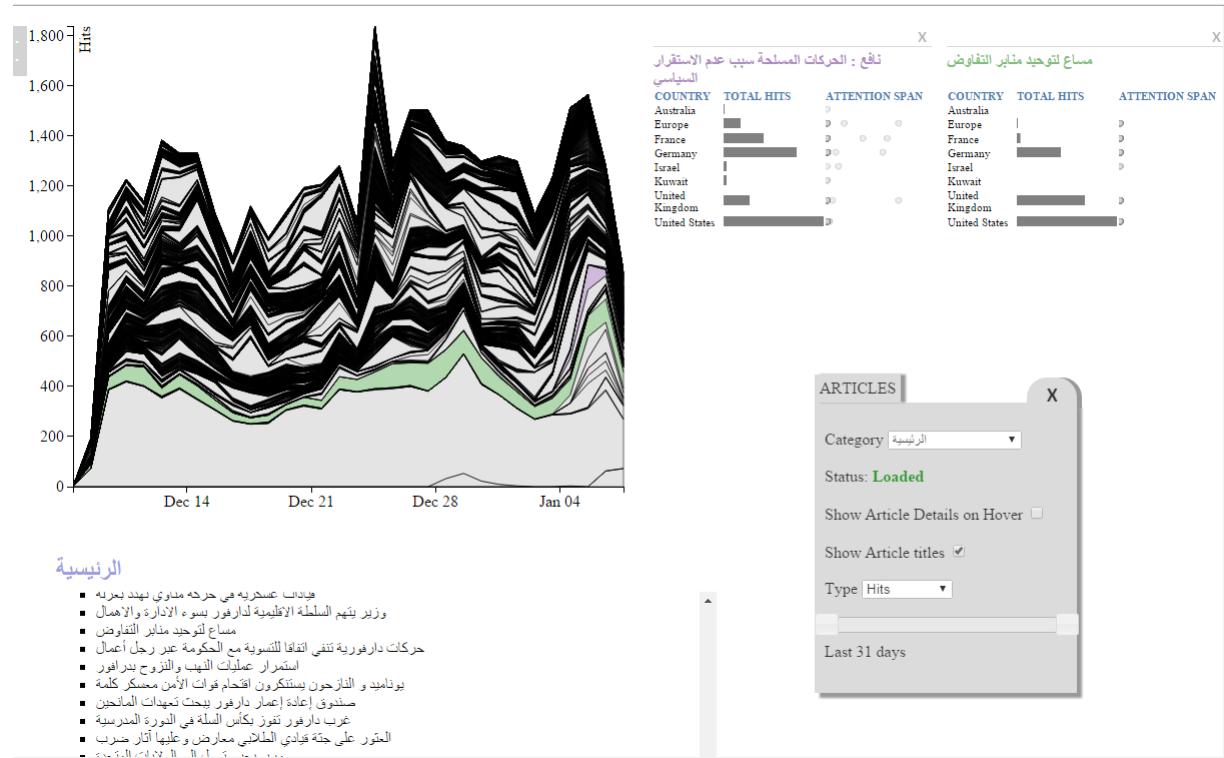

### 8.2.3 Retrieving Web Metrics

- The categories were successfully retrieved in JSON via **getCategories.php**. The pertinent PHP files had to be encoded in UTF-8 to handle the Arabic characters
- The hits data was retrieved successfully from the MySQL database using JSON via **getArticlesMetrics.php**. I initially reserved the geographic data for the articles to be serviced by **getArticleStatesMetrics.php**. However, I felt that in a production environment that many

SQL calls to the database server would slow down the system and affect all users. In order to minimize the number of requests to the server, I had the server fetch all data for a given category for the last 31 days. The client-side Javascript code then parsed and re-organized the fetched data to be used by the interactive visualization

#### 8.2.4 The Interactive Visualization

- The final product included a stacked area chart, a list of article titles, and a right pane for geographic analysis of up to 2 articles

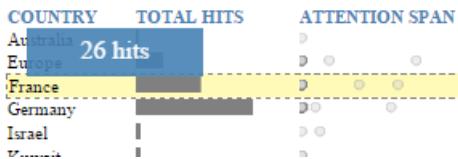

- The hits were aggregated on an hourly basis resulting in Y values over 744 (31 days x 24 hours) X axis time values
- The stacked chart accurately reflected the number of hits and average read time over the selected time range

- Clicking one or more articles highlighted the article encode in the stacked area chart and displayed the total hits based on geography. It also showed the distribution of the recorded read times. Since the target audience of Afia Darfur is an international one, the geographic data was aggregated to countries - unlike in the mock site where units of geography were represented as US states
- The tables that contained the geographic origins were sortable by total hits and by state name - in ascending and descending order
- When "Show Article Details on Hover" was enabled, the pertinent article's thumbnail image, title, and body excerpt were successfully presented in an overlay

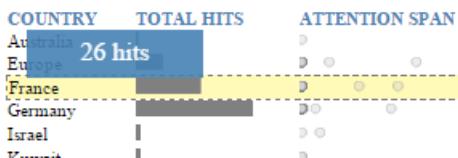

- Hovering over any row in the geographic hits and attention span table resulted in the row being highlighted in yellow for all articles that are being compared

- Hovering over a bar representation of the total number of hits invoked a steel blue overlay showing the number of hits

- Hovering over an attention span circle invoked a steel blue overlay showing the number of seconds that was spent on the article

### 8.2.5 Performance

- In the Afia Darfur website, the last 31 days amounted to 10,000 hits and 40,000 hits for the two main categories being used by the web editors. It took approximately 16 seconds to load the 10,000 hits and 52 seconds to load the 40,000 hits.
- As for adjusting the stacked area graph's time range, there was a 3-second delay for the 10,000 hits and a 10-second delay for the 40,000 hits. This was done using a PC with an Intel i7 processor and 12 GB of RAM. Again, using a PC with an Intel i7 processor and 12 GB of RAM
- When "Show Article Details on Hover" was enabled, there was a delay between 50 to 300 milliseconds for the image thumbnails to initially show. Once they were cached in the browser's memory, they appeared without delay. For images that were not cached, the delay was about 1 second per megabyte in picture size

### **8.2.6 Conclusion**

The stacked area chart would have been more effective with less articles. Looking at 300+ articles simultaneously can be overwhelming. Thus, the web editors need to be directed to submit their articles under appropriate categories. The geographic distribution of hits and contrast between two articles was effective; the only downside was that the read times were not captured for all the hits. Aggregating on an hourly basis resulted in the most practical user experience, while maintaining a good temporal accuracy.

## 9 Future Work

I would have liked to add the following capabilities to my existing visualization:

- To create a stacked area chart for categories over time, similar to the existing one for articles
- To visualize each article's interest fluctuations as a relative measure from its publication date. In the current scenario, one is able to see which articles peak and plunge over time. However, it is difficult to contrast two or more articles' fluctuations since their inception date
- To allow for 4 articles to be simultaneously contrasted across their geographies. I can accomplish this by removing the attention span column and having it as a filter option to narrow the geographic tables
- To visualize per number of hits and attention spans per capita
- To capture social media metrics such as Facebook likes and Twitter tweets, and incorporate them into the stacked area chart

## 10 Glossary

**Apache HTTP Server (aka Apache):** A web server software program

**Choropleth map:** A thematic map in which areas are shaded or patterned in proportion to the measurement of the statistical variable being displayed on the map (source: Wikipedia).

**Class:** In object oriented programming parlance, it refers to the abstraction and representation of a real life object or concept in code.

**CSS:** A styling language used to define the aesthetics of elements in a web deliverable. This is implemented in all major web browsers. CSS3 is the most recent version of this language.

**D3.js:** A JavaScript library for manipulating documents based on data using HTML, SVG and CSS (source: d3js.org).

**Google Analytics:** A service offered by Google that generates detailed statistics about a website's traffic and traffic sources and measures conversions and sales (source: Wikipedia).

**HTML 5:** The most recent specification for the markup language that constitutes the visual elements of any web deliverable. It also normally includes some JavaScript and CSS 3 code as part of its implementation.

**JavaScript:** A client-side scripting language that is used by all prominent web browsers.

**JSON (JavaScript Object Notation):** A lightweight data-interchange format (source: json.org).

**LAMP:** A web development environment comprised of a Linux server, Apache HTTP Server, MySQL, and PHP.

**MySQL:** An open source relational database management system.

**Object oriented programming:** A programming paradigm that represents real-life elements and concepts as "objects". The implementation involves mimicking only the needed real-life characteristics of

the object in code, and calling a working copy of these objects an "instance".

**PHP:** An open source server-side scripting language.

**Relational database:** A database built on principles of the relational model. Such a database is comprised of tables and fields.

**SVG:** An XML-based vector image format for two-dimensional graphics that has support for interactivity and animation (source: Wikipedia).

**Web visualization:** A visual deliverable created using web technologies. More than often, it is dynamic in that it visually changes based on the data being fed to it.
